# Just Enough Spectral Theory

Ng Yen Kaow

#### Notations (Important)

- A vector is by default a column
  - For vectors x and y, their inner (or dot) product,  $\langle x, y \rangle = x^{\top}y$
  - Beware: some texts use row vectors and  $\langle x, y \rangle = xy^{\top}$
- For a matrix an example is a row
  - An example (or datapoint) is a row  $x_i$  while each feature is a columns
    - Features are like fixed columns in a spreadsheet
  - For matrices X and Y,  $\langle X, Y \rangle = XY^{\top}$  or  $\sum_{i} (x_{i}y_{i}^{\top})$
  - Beware: some texts use column for examples and let  $\langle X, Y \rangle = X^{T}Y$
- $\square$  So it's  $x^{\top}x$ ,  $x^{\top}Mx$ , but  $XX^{\top}$  and  $Q\Lambda Q^{\top}$

#### Outer product

The outer product of two vectors x and y is a matrix M where the  $M_{ij} = x_i y_i$ 

e.g. 
$$\binom{a}{b}(c \quad d) = \binom{ac \quad ad}{bc \quad bd}$$

- □ The outer product (or Kronecker product) of two matrices is a tensor
  - We don't deal with tensors yet
- Common uses of outer products

Denote pairwise inner product matrix, 
$$xx^{\top} = \begin{pmatrix} x_1x_1 & x_1x_2 & \dots \\ x_2x_1 & x_2x_2 & \dots \\ \vdots & \vdots & \ddots \end{pmatrix}$$

Denote matrix of all ones,  $\mathbf{11}^{\mathsf{T}} = \begin{bmatrix} 1 & \dots & 1 \\ \vdots & \ddots & \vdots \end{bmatrix}$ 

#### More notations

- Conventions
  - $\mathbf{x}_i$  from a matrix is by default a row vector
  - $\mathbf{x}_i$  from a vector is a scalar
  - $\mathbf{x}_{ij}$  from a matrix is a scalar
  - $\mathbf{x}$ ,  $u_i$  (all other vectors) are by default column vectors
- Common expansions

$$xy^{\top} = \sum_{i} x_{i} y_{i} \qquad (XY)_{ij} = \sum_{k} x_{ik} y_{kj}$$

$$(x^{\top}y)_{ij} = x_{i} y_{j} \qquad (XY^{\top})_{ij} = x_{i} y_{j}^{\top} = \sum_{k} x_{ik} y_{jk}$$

$$x^{\top}My = \sum_{ij} m_{ij} x_{i} y_{j} \qquad (X^{\top}Y)_{ij} = \sum_{k} x_{ki} y_{kj}$$

$$X^{\top}X = \sum_{i} x_{i}^{\top} x_{i} \text{ (used in kernel PCA)}$$

#### Python call for inner product

- □ Inner products are performed with np. dot()
  - When called on two arrays, the arrays are
     automatically oriented to perform inner product
     Note that [[1], [1]] is a 1 × 2 matrix
  - When called on an array x and a matrix X, the array is automatically read as a row for np. dot(x, X), and column for np. dot(X, x) to perform inner product
  - When called on two matrices, make sure that the matrices are oriented correctly, or you will get X<sup>T</sup>X when you want XX<sup>T</sup>
  - Impossible to get outer product with np. dot()
- If you write x\*y or X\*Y, what you get is an element-wise multiplication

#### Eigenvectors and eigenvalues

- Only concerned with square matrices
  - Most matrices we consider are furthermore symmetric and of only real values
- $\square$  A eigenvector for a square matrix M is vector u where  $Mu = \lambda u$ 
  - u is invariant under transformation M
  - The scaling factor  $\lambda$  is a eigenvalue
  - Use u to denote a column vector even when multiple  $u_i$  are collected into a matrix  $U = [u_1 \quad ... \quad u_k]$

#### $Mu = \lambda u$ is a system of equations

- □ An equation such as  $Mu = \lambda u$  actually states n linear equations, namely  $\forall i, \sum_i m_i u_i = \lambda u_i$ 
  - For example

$$\begin{pmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = \lambda \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}$$

states the two equations

$$m_{11}u_1 + m_{12}u_2 = \lambda u_1$$
  
$$m_{21}u_1 + m_{22}u_2 = \lambda u_2$$

- This is important when manipulating equation by multiplying with other matrix/vector
  - For example when  $Mu = \lambda u$  is multiplied from the left by  $u^{\mathsf{T}}$ , the resultant  $u^{\mathsf{T}}Mu = \lambda u^{\mathsf{T}}u$  becomes only one equation, that is,  $\sum_{ij} u_i m_{ij} u_j = \lambda \sum_{ij} u_i u_j$

#### Eigendecomposition

□ A eigendecomposition of matrix M is  $M = Q\Lambda Q^{-1}$ 

where  $\Lambda$  is diagonal, and Q contains (not necessarily orthogonal) eigenvectors of M

- Any normal M can be eigendecomposed
- The set of eigenvalues for *M* is unique
- There can be different eigenvectors of the same eigenvalue (hence not unique)
  - For real symmetric M, eigenvectors that correspond to distinct eigenvalues are (chosen to be) orthogonal

### Orthogonal eigendecomposition

- $\square$  For real symmetric M, can choose Q to be orthogonal matrix (proof omitted)
- $\Box$  For square matrix Q, the following are equivalent (proof next slide)
  - 1. *Q* is an orthogonal matrix
  - 2.  $Q^{T}Q = I$
  - 3.  $QQ^{T} = I$
  - Corollary.  $Q^{T}Q = I \Rightarrow Q^{T}QQ^{-1} = Q^{-1}$  $\Rightarrow Q^{T} = Q^{-1}$

□ By default the eigendecomposition of real symmetric matrix M is  $M = Q\Lambda Q^{\top}$ 

### Orthogonal matrix property

- $\Box$  For square matrix Q, the following are equivalent
  - 1. *Q* is orthogonal matrix
  - 2.  $Q^{T}Q = I$
  - 3.  $QQ^{\mathsf{T}} = I$
  - 2⇔1 Let  $u_i$  be the column vectors of A

$$Q^{\mathsf{T}}Q = \begin{bmatrix} u_1 \\ \vdots \\ u_n \end{bmatrix} \begin{bmatrix} u_1 & \dots & u_n \end{bmatrix} = \begin{bmatrix} u_1u_1 & \dots & u_1u_n \\ \vdots & \ddots & \vdots \\ u_nu_1 & \dots & u_nu_n \end{bmatrix}$$

$$\begin{bmatrix} u_1u_1 & \dots & u_1u_n \\ \vdots & \ddots & \vdots \\ u_nu_1 & \dots & u_nu_n \end{bmatrix} = I \text{ implies } u_iu_j = 0 \text{ for } i \neq j$$

#### Eigenspace

- □ The eigenspace of a matrix M is the set of all the vectors u that fulfills  $Mu = \lambda u$ 
  - The rank of M is its number of non-zero  $\lambda$
- A eigenbasis of a n × n matrix M is a set of n orthogonal eigenvectors of M (including those with zero eigenvalues)
  - Any datapoint  $x_i$  in M can be written as a linear combination of the eigenbasis,  $x_i = \sum_i \langle x_i, u_j \rangle u_j$
  - Any eigenvector  $u_i$  for M can be written as a linear combination of the datapoints  $x_i$ , by solving the system of equations  $x_i = \sum_i \langle x_i, u_i \rangle u_i$

## Rayleigh Quotient

- $\Box \frac{u^{\mathsf{T}} M u}{u^{\mathsf{T}} u}$  is called the **Rayleigh quotient**
- □ Let  $\lambda_1,...,\lambda_n$  where  $\lambda_1 \ge \lambda_2 \ge ... \ge \lambda_n$  be the eigenvalues of M
- Min-max Theorem (simplified)
  - Maximum of the Rayleigh quotient,

$$\max_{\|u\|=1} \frac{u^{\mathsf{T}} M u}{u^{\mathsf{T}} u} = \lambda_1$$

Minimum of the Rayleigh quotient,

$$\min_{\|u\|=1} \frac{u^{\mathsf{T}} M u}{u^{\mathsf{T}} u} = \lambda_n$$

#### Proof of min-max theorem

- □ Find stationary points of  $\frac{u^T M u}{u^T u}$
- □ Letting u' = cu does not change  $\frac{u^{\mathsf{T}}Mu}{u^{\mathsf{T}}u} \left( = \frac{u'^{\mathsf{T}}Mu'}{u'^{\mathsf{T}}u'} \right)$ 
  - Hence consider only unit u
  - Maximize  $u^{\mathsf{T}} M u$  subject to  $u^{\mathsf{T}} u = 1$
- □ Use Lagrangian to add  $u^Tu = 1$  constraint

$$\mathcal{L}(u,\lambda) = u^{\mathsf{T}} M u + \lambda (u^{\mathsf{T}} u - 1)$$

$$\frac{\partial \mathcal{L}}{\partial u} = u^{\mathsf{T}} (M + M^{\mathsf{T}}) + 2\lambda u^{\mathsf{T}} = 0$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = u^{\mathsf{T}} u - 1 = 0$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = u^{\mathsf{T}} u - 1 = 0$$
Matrix differentiation\*
$$\frac{\partial x^{\mathsf{T}} M x}{\partial x} = x^{\mathsf{T}} (M + M^{\mathsf{T}})$$

$$\frac{\partial x^{\mathsf{T}} M x}{\partial x} = 2x^{\mathsf{T}}$$

$$u^{\mathsf{T}}(M + M^{\mathsf{T}}) = -2\lambda u^{\mathsf{T}} \Rightarrow (M + M^{\mathsf{T}})u = -2\lambda u$$

Since *M* is symmetric,  $2Mu = -2\lambda u$ 

$$\Rightarrow Mu = \tilde{\lambda}u \text{ where } \tilde{\lambda} = -2\lambda$$

□ Stationary points are solutions of  $Mu = \tilde{\lambda}u$ 

### Eigendecomposition applications

- Matrix inverse
- Matrix approximation
- Matrix factorization
  - Multidimensional Scaling
- Minimizing/maximizing Rayleigh Quotient
  - PCA
    - Max of covariance matrix
  - Spectral clustering
    - Min of graph Laplacian

## Singular Value Decomposition

- Any matrix can be singular value decomposed
- $\square$   $M = USV^*$ 
  - lacksquare M is  $m \times n$  matrix
  - lacksquare U is an  $m \times m$  unitary matrix
  - lacksquare S is an  $m \times n$  diagonal matrix
  - lacksquare V is an  $n \times n$  unitary matrix
- □ For a real M,  $V^* = V^\top$  (and  $U = U^\top$ ) hence  $M = USV^\top$

For unitary matrix U,  $UU^* = U^*U = I$ 

## **SVD** applications

- Solving linear equations
- Linear regression
- Pseudoinverse
- Kabsch algorithm
- Matrix approximation
- As a eigendecomposition (see next slide)

### SVD and eigendecomposition

- □ SVD of matrix M simultaneously performs a eigendecomposition of  $M^TM$  and  $MM^T$ 
  - $M^{T}M$  and  $MM^{T}$  are important matrices (next slide)
  - Given SVD of  $M = USV^{T}$ , since V and U are unitary
    - $\square M^{\mathsf{T}}M = VS^{\mathsf{T}}U^{\mathsf{T}}USV^{\mathsf{T}} = V(S^{\mathsf{T}}S)V^{\mathsf{T}} = VS^{2}V^{\mathsf{T}}$
    - $\square MM^{\mathsf{T}} = USV^{\mathsf{T}}VS^{\mathsf{T}}U^{\mathsf{T}} = U(S^{\mathsf{T}}S)U^{\mathsf{T}} = US^{2}U^{\mathsf{T}}$
    - $\Rightarrow$  V is the eigenbasis of  $M^{\top}M$  and U is the eigenbasis of  $MM^{\top}$  respectively
    - $\Rightarrow M^{\top}M$  and  $MM^{\top}$  have the same eigenvalues, namely  $S^2$

#### **Special Matrices**

- Three types of matrices lead to many results
  - Covariance  $(A^TA \text{ for column centered } A)$ 
    - ⇒ Principal Component Analysis
  - Gramian  $(AA^{\mathsf{T}}$  for column centered A)
    - ⇒ Multidimensional Scaling
    - ⇒ Kernel Method
  - Graph Laplacian  $(AA^{T})$  for incidence matrix A)
    - ⇒ Spectral Clustering
